Abstract: In this paper, we show that the high frequency modes of a thin clamped plate and the associated eigenfunctions converge, as the thickness of the plate goes to zero, to the eigenvalues and the eigenfunctions of a two-dimensional eigenvalue problem associated to the stretching displacements of the plate.

Keywords: linear elasticity; asymptotic analysis; thin plates; eigenvalue problem; high frequency modes; stretching vibrations

Mathematics Subject Classification: 35E20, 35C20, 74B05, 74K20, 74G10

1. Introduction

The purpose of this article is to study the asymptotic behavior of the high frequency modes of thin plates when the thickness of the plates goes to zero. The asymptotic methods were used to study a large variety of problems in thin elastic structures. Let us refer to Ciarlet and Destunder [1] for the justification of the two-dimensional linear plate model, Ciarlet et al. [2] for the junctions between three-dimensional and two-dimensional linear elastic structures, Le Dret [3, 4] for modeling of a folded plate and [5] for modeling of the junction between two rods, and Trabucho and Viaño [6] for asymptotic analysis of linearized elastic beams.

The problem of modeling the vibrations of thin elastic structures using a rigorous asymptotic technique was first done by Ciarlet and Kessavan [7] in the case of a clamped plate. The techniques introduced in this article were adapted and used to study different spectral problems: Le Dret [8] for the vibrations of a folded plate, Bourquin and Ciarlet [9] and Lods [10] for a plate inserted in a three-dimensional body, Kerdid [11, 12] for a single rod and junction between two rods. All these works are concerned with the convergence of low frequency modes of the three-dimensional linear elasticity, as the thickness of the body tends to zero. The limit problems obtained are the classical spectral problems associated with the flexural displacement of the structure. However, these techniques fail to obtain the
limit problem for higher frequency modes.

We also refer to some interesting works related to this article, which deal with the asymptotic analysis of the eigenvalue problem in different thin linear elastic structures: Jumbo and Rodriguez Mulet [13] and Jumbo et al. [14] for thin elastic rod with non-uniform cross-section, Serpilli and Lenci [15] for laminated beams, Tambača [16] for curved rods and Qaudiello et al. [17] for a thin T-like shaped structure.

A nonstandard technique has been proposed in Irago et al. [18,19] to study the behavior of the high frequency modes and their associated eigenfunctions in thin elastic rods. The limit problem obtained is the coupled one-dimensional spectral problem giving the classical equations for torsion and stretching vibrations.

In this work, we combine the techniques of [7, 19] to study the asymptotic behavior of high frequency modes in a thin clamped plate when the thickness of the plate goes to zero. Indeed, we will construct a suitable families of index \( \{ \ell_m^\varepsilon \} \), which varies with \( \ell \) and \( \varepsilon \), and for which the high frequency eigenvalues \( \eta_{m}^{\varepsilon} \) converge when the thickness of the plate approaches zero towards the eigenvalues \( \eta_{m} \) of a two-dimensional spectral problem. The limit problem is identified to be the standard eigenvalue problem associated with the classical equations for stretching vibrations of the plate. The limit eigenfunctions are determined by the couples \( (\zeta_{m}^{1}, \zeta_{m}^{2}) \) of functions of the longitudinal variables of the plate that are the unique solution of the limit problem and correspond to the stretching displacements of the plate.

### 2. The three-dimensional problem

Let \( \omega \) be an open bounded set of \( \mathbb{R}^2 \) and \( \gamma = \partial \omega \) its boundary which is assumed to be sufficiently smooth. Given \( \varepsilon \geq 0 \) we define

\[
\Omega_{\varepsilon} = \omega \times (-\varepsilon, \varepsilon), \quad \Gamma_{\varepsilon} = \gamma \times (-\varepsilon, \varepsilon).
\] (2.1)

\( \Omega_{\varepsilon} \) is assumed to be the reference configuration of the plate under consideration. The plate is clamped on its boundary \( \Gamma_{\varepsilon} \). The material that constitute the plate is assumed to be homogeneous and isotropic with Young’s modulus \( E \) and Poisson’s ratio \( \nu \), all independent of \( \varepsilon \).

We will also use the Lame’s coefficients \( \lambda \) and \( \mu \) related to \( E \) and \( \nu \) by the formulas:

\[
\lambda = \frac{\nu E}{(1 + \nu)(1 - 2\nu)}, \quad \mu = \frac{E}{2(1 + \nu)}.
\] (2.2)

In the sequel, we shall use the repeated index convention, the Greek indices take their values in the set \{1, 2\} and the Latin indices take their values in the set \{1, 2, 3\}.

The classical eigenvalue problem for the plate under consideration consists in finding pairs \( (\eta^\varepsilon, u^\varepsilon) \) satisfying:

\[
\begin{aligned}
-\partial_j \sigma^\varepsilon_{ij} &= \eta^\varepsilon u^\varepsilon_i \quad \text{in} \ \Omega_{\varepsilon}, \\
\sigma^\varepsilon_{ij}(u^\varepsilon) &= \lambda \varepsilon^{pp}_{ij}(u^\varepsilon)\delta_{ij} + 2\mu \varepsilon_{ij}(u^\varepsilon) \quad \text{in} \ \Omega_{\varepsilon}, \\
u^\varepsilon &= 0 \quad \text{on} \ \Gamma_{\varepsilon}, \\
\sigma^\varepsilon n^\varepsilon &= 0 \quad \text{on} \ \partial \Omega_{\varepsilon}\setminus \Gamma_{\varepsilon},
\end{aligned}
\] (2.3)
where $\sigma^\varepsilon(u^\varepsilon)$ is the stress tensor, $n^\varepsilon$ is the outer unit normal vector to $\partial \Omega^\varepsilon$, and $e^\varepsilon(u^\varepsilon)$ is the linearized strain tensor corresponding to the displacement $u^\varepsilon$:

$$e^\varepsilon_{ij}(u^\varepsilon) = \frac{1}{2} \left( \frac{\partial u^\varepsilon_j}{\partial x_i} + \frac{\partial u^\varepsilon_i}{\partial x_j} \right).$$

(2.4)

In order to put the above problem in variational form, we introduce the space

$$V^\varepsilon = \{ v^\varepsilon = (v^\varepsilon_i) \in [H^1(\Omega^\varepsilon)]^3, \quad v^\varepsilon = 0 \quad \text{on } \Gamma^\varepsilon \}. $$

(2.5)

So, problem (2.3) is equivalent to finding $(\eta^\varepsilon, u^\varepsilon) \in \mathbb{R} \times V^\varepsilon$ satisfying

$$\int_{\Omega^\varepsilon} \sigma^\varepsilon_{ij}(u^\varepsilon)e^\varepsilon_{ij}(v^\varepsilon) \, dx = \eta^\varepsilon \int_{\Omega^\varepsilon} u^\varepsilon_i v^\varepsilon_i \, dx \quad \forall v^\varepsilon \in V^\varepsilon. $$

(2.6)

Thanks to Korn inequality, the bilinear form

$$(u^\varepsilon, v^\varepsilon) \in V^\varepsilon \times V^\varepsilon \mapsto \int_{\Omega^\varepsilon} \sigma^\varepsilon_{ij}(u^\varepsilon)e^\varepsilon_{ij}(v^\varepsilon) \, dx$$

(2.7)

is $V^\varepsilon$-elliptic. From spectral theory, it is known that problem (2.6) has a sequence of eigenvalues $(\eta^\varepsilon_m)_{m \geq 1}$ satisfying

$$0 < \eta^\varepsilon_1 \leq \eta^\varepsilon_2 \leq \eta^\varepsilon_3 \leq \ldots \leq \eta^\varepsilon_m \leq \ldots$$

(2.8)

with

$$\lim_{m \to \infty} \eta^\varepsilon_m = +\infty,$$

(2.9)

associated with a family of eigenfunctions $(u^\varepsilon_m)_{m \geq 1}$, that is

$$\int_{\Omega^\varepsilon} \sigma^\varepsilon_{ij}(u^\varepsilon_m)e^\varepsilon_{ij}(v^\varepsilon) \, dx = \eta^\varepsilon_m \int_{\Omega^\varepsilon} u^\varepsilon_m v^\varepsilon_i \, dx \quad \forall v^\varepsilon \in V^\varepsilon, $$

(2.10)

which can be orthonormalized as

$$\int_{\Omega^\varepsilon} u^\varepsilon_m u^\varepsilon_n \, dx = \delta_{mn} \quad \forall m, n \geq 1, $$

(2.11)

and which make a basis in both Hilbert spaces $V^\varepsilon$ and $[L^2(\Omega^\varepsilon)]^3$.

3. The scaled problem

In order to define a problem equivalent to problem (2.6) but posed over a domain which does not depend on $\varepsilon$, we let

$$\Omega = \omega \times (-1, 1), \quad \Gamma = \gamma \times (-1, 1), $$

(3.1)

and

$$V = H^1_0(\Omega; \mathbb{R}^3). $$

(3.2)

We introduce the following mapping:

$$\phi^\varepsilon : \Omega \rightarrow \Omega^\varepsilon,$$
and the scaling functions \( v(\varepsilon) \in V \) defined as:

\[
v_\alpha(\varepsilon)(x) = \varepsilon^{-1}v_\alpha^\varepsilon(x^\varepsilon);
\]

\[
v_3(\varepsilon)(x) = v_3^\varepsilon(x^\varepsilon).
\]

Due to scaling, we have

\[
\begin{align*}
\varepsilon_{\alpha\beta}^\varepsilon(v^\varepsilon) &= \varepsilon_{\alpha\beta}^\varepsilon(v), \\
\varepsilon_{\alpha 3}^\varepsilon(v^\varepsilon) &= \varepsilon^{-1}\varepsilon_{\alpha 3}^\varepsilon(v), \\
e_{33}^\varepsilon(v^\varepsilon) &= \varepsilon^{-2}e_{33}^\varepsilon(v).
\end{align*}
\]

(3.4)

Substituting (3.4) in (2.6), we obtain the following scaled variational formulation:

Find \((\eta_m(\varepsilon), u_m(\varepsilon)) \in \mathbb{R} \times V\) such that for all \(v \in V\)

\[
\int_\Omega b_\varepsilon(u_m(\varepsilon), v)dx = \eta_m(\varepsilon) \left\{ \int_\Omega u_{\alpha}^m(\varepsilon)v_\alpha dx + \varepsilon^{-2}\int_\Omega u_{3}^m(\varepsilon)v_3 dx \right\},
\]

(3.5)

where

\[
\eta_m(\varepsilon) = \eta_m^\varepsilon,
\]

(3.6)

and

\[
b_\varepsilon(u, v) = 2\mu e_{\alpha\beta}(u)e_{\alpha\beta}(v) + \lambda e_{\alpha\alpha}(u)e_{\beta\beta}(v) + \varepsilon^{-2}\left[ 4\mu e_{\alpha 3}(u)e_{\alpha 3}(v) + \lambda(e_{\alpha\alpha}(u)e_{33}(v) + e_{33}(u)e_{\alpha\alpha}(v)) \right] + \varepsilon^{-4}(\lambda + 2\mu)e_{33}(u)e_{33}(v),
\]

(3.7)

with the normalization condition

\[
\int_\Omega u_{\alpha}^m(\varepsilon)u_{\alpha}^n(\varepsilon)dx + \varepsilon^{-2}\int_\Omega u_{3}^m(\varepsilon)u_{3}^n(\varepsilon)dx = \delta_{mn} \quad \forall m, n \geq 1.
\]

(3.8)

We define the space of Kirchhoff-Love on \(\Omega\) as

\[
V_{KL} = \{v \in V, \quad e_{33}(v) = 0\}.
\]

(3.9)

Elements of this space are characterized by

\[
\begin{align*}
v_\alpha(0)(x) &= \zeta_\alpha(x_1, x_2) - x_3\partial_\alpha\zeta_3(x_1, x_2), \\
v_3(0)(x) &= \zeta_3(x_1, x_2),
\end{align*}
\]

(3.10)

where \(\zeta_\alpha \in H^1(\omega)\) and \(\zeta_3 \in H^2(\omega)\).

4. Convergence of low frequency modes

A first convergence analysis of the low frequencies of the three-dimensional linearized elasticity system in a thin plate, when the thickness of the plate approaches zero, was done in [7]. It has been shown that the standard biharmonic two-dimensional eigenvalue problem associated with the flexural displacements of the plate can be derived mathematically from the standard three-dimensional eigenvalue problem of linear elasticity through a rigorous convergence analysis as the thickness of the plate tends to zero.
More precisely, it has been proven that for each integer \( m \geq 1 \),

\[
\lambda_m(\varepsilon) = \varepsilon^{-2} \eta_m(\varepsilon) \to \lambda_m(0) \quad (4.1)
\]

and

\[
u^m(\varepsilon) \to \nu^m(0) \quad \text{strongly in } V \quad (4.2)
\]

with

\[
u^m(0) = (-x_3 \partial_1 u_3^m(x_1, x_2), -x_3 \partial_2 u_3^m(x_1, x_2), u_3^m(x_1, x_2)),
\]

where \((\lambda_m(0), u_3^m) \in \mathbb{R} \times H^2_0(\omega)\) are eigensolutions of the limit spectral problem:

Find \((\lambda, u) \in \mathbb{R} \times H^2_0(\omega)\) such that, for all \( v \in H^2_0(\omega)\)

\[
\frac{E}{3(1 - \nu^2)} \int_\omega \Delta u \Delta v dx_1 dx_2 = \lambda \int_\omega uv dx_1 dx_2. \quad (4.3)
\]

The pairs \((\lambda^m(0), u_3^m)\) are solutions of the eigenvalue problem for the biharmonic operator \(\Delta^2\)

\[
\frac{E}{3(1 - \nu^2)} \Delta^2 u = \lambda u, \quad (4.4)
\]

corresponding to the classical equations for the flexural vibrations.

5. Convergence of high frequency modes

Our objective in this work is to characterize the limit problem associated to high frequency modes when the thickness of the plate goes to zero. Unfortunately, the techniques used in [7] are not adapted for the asymptotic analysis of higher frequency modes. So, we will be inspired by the idea proposed in [18, 19] for the convergence analysis of high frequencies in a thin rod in order to characterize the limit problem for high frequency modes in a thin plate.

Let us start with the following lemma:

**Lemma 5.1.** There exists an increasing sequence of constants \( K_m \) \( m \geq 1 \), \( \varepsilon \) independent of \( \varepsilon \) such that

\[
\eta_m(\varepsilon) \leq K_m \varepsilon^2. \quad (5.1)
\]

**Proof.** From [7] Lemma 1 we have, for each integer \( m \geq 1 \), \( \varepsilon^{-2} \eta_m(\varepsilon) \leq K_m \) where \( K_m \) is a constant independent of \( \varepsilon \), which gives (5.1). \( \square \)

So, if we fix the index \( m \) and we make \( \varepsilon \) tend to zero, all the sequence \( \eta_m(\varepsilon) \) goes to zero. indeed, the high frequency modes are concentrated at infinity when \( \varepsilon \) approaches zero and cannot be obtained using such a passage to the limit. So, the idea in order to characterize this kind of frequencies, consists in associating to each integer \( m \geq 1 \), a family of index \( \{\ell_m(\varepsilon) \}_{\varepsilon > 0} \) that depend on \( \varepsilon \) and such that

\[
\lim_{\varepsilon \to 0} \ell_m(\varepsilon) = +\infty, \quad (5.2)
\]

and

\[
\eta_{\ell_m}(\varepsilon) < K_m. \quad (5.3)
\]
This family of index can be defined by
\[ \ell_{\varv}^m = \max\{ j \in \mathbb{N}^* : \eta_j(\varv) \leq K_m \}. \] (5.4)

It is clear that (5.4) satisfies (5.2) and (5.3).

The family of index \( \{\ell_{\varv}^m\} \) varies with \( m \) and \( \varv \), and for each \( \varv > 0 \), \( \{\ell_{\varv}^m\}_{m \geq 1} \) is an increasing subsequence of positive integers satisfying \( \ell_{\varv}^m \geq m, \forall m \geq 1 \). It contains the indices of the stretching modes among all the modes \( \{\eta_m(\varv)\}_{m \geq 1} \) of the plate.

To illustrate this idea and show the layout of the stretching modes \( \{\eta_{\ell}(\varv)\} \) when \( m \) and \( \varv \) vary, let us represent the family \( \{\eta_{\ell}(\varv)\} \) in a double-entry table. Consider a decreasing sequence \( \{\nu_n\}_{n \geq 1} \) converging to 0, the elements of the sequences \( \{\eta_{\nu_n}(\varv)\}_{n \geq 1} \) are arranged in rows while the elements of the sequences \( \{\eta_m(\varv)\}_{m \geq 1} \) are arranged in columns.

\[
\begin{array}{ccccccc}
\eta_1(\nu_1) & \cdots & \eta_{\nu_1}(\nu_1) & \cdots & \eta_{\nu_{\nu_1}}(\nu_1) & \cdots \\
\eta_1(\nu_2) & \cdots & \eta_{\nu_2}(\nu_2) & \cdots & \eta_{\nu_{\nu_2}}(\nu_2) & \cdots \\
\vdots & & \cdots & & \cdots & \\
\eta_1(\nu_n) & \cdots & \eta_{\nu_n}(\nu_n) & \cdots & \eta_{\nu_{\nu_n}}(\nu_n) & \cdots \\
\downarrow & & & & \downarrow & \\
0 & \cdots & \eta_{\nu_{\nu_n}}(0) & \cdots & \eta_{\nu_{\nu_{\nu_n}}}(0) & \cdots \\
\end{array}
\]

Since for each \( m \geq 1 \) the family \( \{\ell_{\varv}^m\}_{n \geq 1} \) is increasing, that is \( \ell_{\varv}^m \geq \ell_{\varv}^{m'} \) for \( n > n' \), the elements of the sequence \( \{\eta_{\ell_{\varv}^m}(\nu_n)\}_{n \geq 1} \) corresponding to the modes associated to the stretching vibrations of the plate are arranged diagonally. As the stretching vibrations are high frequency modes and are concentrated at infinity when \( \varv \) approaches zero, they can only be reached through such a family of indices.

The following theorem summarize the results obtained when passing to the limit on these families of sequences and constitute the main result of this paper.

**Theorem 5.2.** For each integer \( m \geq 1 \), there exists a sequence \( \{\ell_{\varv}^m\} \) such that
\[ \eta_{\ell_{\varv}^m}(\varv) \to \eta_m(0) \] (5.5)

where \( \eta_m(0) \) is an eigenvalue of the limit spectral problem:

Find \( (\eta, \zeta) \in \mathbb{R} \times [H^1_0(\omega)]^2 \) such that, for all \( \xi \in [H^1_0(\omega)]^2 \),
\[
\frac{E}{1 + \nu} \int_\omega e_{\alpha\beta}(\xi)e_{\alpha\beta}(\eta)dx_1dx_2 + \frac{Ev}{1 - \nu^2} \int_\omega e_{\alpha\gamma}(\xi)e_{\beta\gamma}(\eta)dx_1dx_2 = \eta(0) \int_\omega \xi_\alpha \xi_\alpha dx_1dx_2. \tag{5.6}
\]

In addition, there exists a subsequence (still denoted \( \varv \)) and \( u^m(0) \in V \) such that
\[ u^{\ell_{\varv}^m}(\varv) \to u^m(0) \quad \text{weakly in } V, \tag{5.7} \]

where
\[ u_{\alpha}(0) = \xi_{\alpha}(x_1, x_2) \tag{5.8} \]

and
\[ u_{\gamma}(0) = 0. \tag{5.9} \]
with
\[(\xi^m_1, \xi^m_2) \in [H^1_0(\omega)]^2.\]

If \((\xi^m_1, \xi^m_2) \neq (0, 0)\) then it is an eigenfunction associated to \(\eta_m(0)\).

To prove this theorem we combine the techniques in [7, 19]. First, we start by establishing an appropriate bound for the eigenfunctions.

**Lemma 5.3.** For each \(m \geq 1\), there exists a constant \(C_m > 0\) independent of \(\varepsilon\), such that
\[
\| u^m(\varepsilon) \|_{H^1(\Omega; \mathbb{R}^3)} \leq C_m. \tag{5.10}
\]

**Proof.** Let us define the scaled strain tensors
\[
\begin{align*}
\kappa^m_{ij}(\varepsilon) &= \varepsilon_{ij}^0(u^m(\varepsilon)), \\
\kappa^m_{ij}(\varepsilon) &= \varepsilon^{-1}\varepsilon_{ij}^0(u^m(\varepsilon)), \\
\kappa^m_{33}(\varepsilon) &= \varepsilon^{-2}\varepsilon_{33}^0(u^m(\varepsilon)).
\end{align*} \tag{5.11}
\]

Taking \(v = u^m(\varepsilon)\) in (3.5) and using (3.7) and (3.8), we obtain
\[
2\mu\| \kappa^m(\varepsilon) \|_{L^2(\Omega; \mathbb{R}^3)} \leq \int_{\Omega} b(\varepsilon, u^m(\varepsilon), u^m(\varepsilon)) \, dx_1 \, dx_2 = \eta^m(\varepsilon) \leq K_m.
\]

So, we have
\[
\| \kappa^m_{ij}(\varepsilon) \|_{L^2(\Omega)} \leq C_m, \tag{5.12}
\]
and consequently, since \(0 < \varepsilon \leq 1\),
\[
\begin{align*}
\| \varepsilon_{ij}^0(u^m(\varepsilon)) \|_{L^2(\Omega)} &\leq C_m, \\
\| \varepsilon_{ij}^0(u^m(\varepsilon)) \|_{L^2(\Omega)} &\leq C_m \varepsilon \leq C_m, \\
\| \varepsilon_{33}^0(u^m(\varepsilon)) \|_{L^2(\Omega)} &\leq C_m \varepsilon^2 \leq C_m.
\end{align*} \tag{5.13}
\]

Therefore, (5.10) is obtained using Korn inequality in \(H^1_0(\Omega; \mathbb{R}^3)\). \(\square\)

**Lemma 5.4.** For each \(m \geq 1\), there exists a subsequence (still denoted \(\varepsilon\)) such that
\[
\eta^m(\varepsilon) \to \eta_m(0) \tag{5.14}
\]
and
\[
u^m(\varepsilon) \rightharpoonup u^m(0) \quad \text{weakly in } V \tag{5.15}
\]
where
\[
u^m_\alpha(0)(x) = \xi^m_\alpha(x_1, x_2) - x_3 \partial_\alpha \xi^m_3(x_1, x_2), \tag{5.16}
\]
\[
u^m_3(0)(x) = \xi^m_3(x_1, x_2), \tag{5.17}
\]
with \(\xi_\alpha \in H^1_0(\omega)\) and \(\xi_3 \in H^1_0(\omega)\).
Proof. Convergences (5.14) and (5.15) come from (5.3) and (5.10). Now using (5.13) we have
\[ e_{i3}(u^m(\varepsilon)) \to 0 \quad \text{strongly in } L^2(\Omega), \]
and since
\[ u_3^m(\varepsilon) \to u_3^m(0) \quad \text{weakly in } H^1(\Omega), \]
then
\[ e_{i3}(u^m(\varepsilon)) \to e_{i3}(u^m(0)) \quad \text{weakly in } L^2(\Omega). \]
Thus,
\[ e_{i3}(u^m(0)) = 0. \]
Therefore, \( u^m(0) \in V_{KL} \) and consequently, we deduce (5.16) and (5.17) from (3.10). \( \square \)

**Lemma 5.5.** For each \( m \geq 1 \), if \( \eta_m(0) \neq 0 \) then
\[ \zeta_3^m = 0. \quad (5.18) \]

**Proof.** Let \( v = (0, 0, v_3) \), \( v_3 \in H^1_0(\omega) \) we have
\[ e_{o\beta}(v) = 0, \quad e_{o3}(v) = \frac{1}{2} \partial_\alpha v_3, \quad \text{and } e_{33}(v) = 0. \]
Substituting in (3.5) and multiplying the equation by \( e^2 \) we have
\[ \varepsilon \int_{\Omega} 2\mu \kappa_{33}^m(\varepsilon) \partial_\alpha v_3 dx = \eta_m(\varepsilon) \int_{\Omega} u_3^m(\varepsilon)v_3 dx. \]
Passing to the limit as \( \varepsilon \to 0 \), we obtain
\[ \int_\omega \zeta_3^m v_3 dx_1 dx_2 = 0 \quad \forall v_3 \in H^1_0(\omega). \]
Therefore,
\[ \zeta_3^m = 0. \quad \square \]

**Lemma 5.6.** For each \( m \geq 1 \), there exists a subsequence (still denoted \( \varepsilon \)) such that
\[ \kappa_{m}^m(\varepsilon) \to \kappa_{m}^m(0) \quad \text{weakly in } L^2(\Omega), \quad (5.19) \]
with
\[ \kappa_{o\beta}^m(0) = e_{o\beta}(\varepsilon^m), \quad (5.20) \]
and
\[ \kappa_{o3}^m(0) = 0. \quad (5.21) \]
Proof. Convergence (5.19) comes from (5.12) and from (5.15) we have
\[\kappa_{a\beta}^m(\varepsilon) \rightharpoonup e_{a\beta}(u^m(0)) \text{ weakly in } L^2(\Omega).\] (5.22)
Using (5.16) and (5.18) we obtain
\[u^m_a(0) = \zeta^m_a(x_1, x_2),\]
and then
\[\kappa_{m\alpha}^\varepsilon(0) = e_{m\alpha}(\varepsilon).\]
Taking now \(v = (v_1, v_2, 0)\) in (3.5), with \(v_\alpha \in H^1_\Gamma(\Omega)\), and multiplying the equation by \(\varepsilon\), we obtain
\[\varepsilon \int_\Omega \left[ 4\mu \kappa_{a\beta}^m(\varepsilon) e_{a\beta}(v) + \kappa_{a\alpha}^m(\varepsilon) e_{a\alpha}(v) \right] dx + 4\mu \int_\Omega \kappa_{a\beta}^m(\varepsilon) e_{a\beta}(v) dx + \varepsilon \lambda \int_\Omega \kappa_{m\alpha}^\varepsilon(\varepsilon) e_{m\alpha}(v) dx = \varepsilon \eta_m(\varepsilon) \int_\Omega u^m_a(\varepsilon)v dx.\] (5.23)
Passing to the limit as \(\varepsilon \to 0\), we obtain
\[4\mu \int_\Omega \kappa_{a\beta}^m(0) \partial_3 v_\alpha dx = 0, \quad \forall v_\alpha \in H^1_\Gamma(\Omega),\]
which has as unique solution (see [8])
\[\kappa_{a\beta}^m(0) = 0.\]

\[\square\]

Lemma 5.7. For each \(m \geq 1\), there exists a subsequence, still denoted \(\varepsilon\), such that
\[\kappa_{33}^m(\varepsilon) \rightharpoonup \kappa_{33}^m(0) \text{ weakly in } L^2(\Omega)\] (5.24)
where
\[\kappa_{33}^m(0) = \frac{-\lambda}{\lambda + 2\mu} \kappa_{a\alpha}^m(0).\] (5.25)
Proof. Let \(v = (0, 0, v_3), \ v_3 \in H^1_\Gamma(\Omega)\), we have
\[e_{a\beta}(v) = 0 \text{ and } e_{a\alpha}(v) = \frac{1}{2} \partial_\alpha v_3.\]
Substituting in (3.5) and multiplying the equation by \(\varepsilon^2\), we obtain
\[\varepsilon \int_\Omega \left[ 2\mu \kappa_{a\beta}^m(\varepsilon) \partial_\alpha v_\beta dx + \lambda \int_\Omega \kappa_{a\alpha}^m(\varepsilon) \partial_3 v_\alpha dx \right] + (\lambda + 2\mu) \int_\Omega \kappa_{33}^m(\varepsilon) \partial_3 v_3 dx = \eta_m(\varepsilon) \int_\Omega u^m_a(\varepsilon) v_3 dx.\]
Which gives by passing to the limit as \(\varepsilon \to 0\)
\[\int_\Omega \left[ \lambda \kappa_{a\alpha}^m(0) + (\lambda + 2\mu) \kappa_{33}^m(0) \right] \partial_3 v_\alpha dx = 0, \quad \forall v_\alpha \in H^1_\Gamma(\Omega),\]
and consequently,
\[\lambda \kappa_{a\alpha}^m(0) + (\lambda + 2\mu) \kappa_{33}^m(0) = 0.\]

\[\square\]
Lemma 5.8. The stretching displacements \((\xi_1^m, \xi_2^m) \in [H^1_0(\omega)]^2\) satisfy for all \((\xi_1, \xi_2) \in [H^1_0(\omega)]^2\),

\[
\frac{E}{1 + \nu} \int_\omega e_{\alpha\beta}(\xi^m) e_{\alpha\beta}(\xi) d\omega d\eta + \frac{E\nu}{1 - \nu^2} \int_\omega e_{\alpha\alpha}(\xi^m) e_{\beta\beta}(\xi) d\omega d\eta = \eta_m(0) \int_\omega \xi_\alpha^m \xi_\alpha d\omega d\eta,
\]

(5.26)

Proof. Taking \(v = (\xi_1, \xi_2, 0)\) in (3.5) with \((\xi_1, \xi_2) \in [H^1_0(\omega)]^2\), we have

\[
\int_\Omega \left[ 2\mu \kappa_{\alpha\beta}^m(e) e_{\alpha\beta}(v) + \lambda \kappa_{\alpha\alpha}^m(e) e_{\beta\beta}(v) \right] d\omega + \int_\Omega \lambda e_{\alpha\beta}(\xi) e_{\beta\alpha}(v) d\omega = \eta_m(e) \int_\Omega u_\alpha^m(\xi) v_\alpha d\omega.
\]

Passing to the limit when \(\varepsilon \to 0\), we obtain

\[
2\mu \int_\Omega \kappa_{\alpha\alpha}^m(0) e_{\alpha\alpha}(\xi) d\omega d\eta + \lambda \int_\Omega \kappa_{\alpha\beta}^m(0) e_{\beta\beta}(\xi) d\omega d\eta = \eta_m(0) \int_\Omega u_\alpha^m(0) \xi_\alpha d\omega d\eta,
\]

which can be written, using (5.25)

\[
2\mu \int_\Omega \kappa_{\alpha\alpha}^m(0) e_{\alpha\alpha}(\xi) d\omega d\eta + \frac{2\mu\lambda}{\lambda + 2\mu} \int_\Omega \kappa_{\alpha\beta}^m(0) e_{\beta\beta}(\xi) d\omega d\eta = \eta_m(0) \int_\Omega u_\alpha^m(0) \xi_\alpha d\omega d\eta.
\]

Replacing \(\kappa_{\alpha\beta}^m(0)\) by their expressions (5.20), we obtain

\[
2\mu \int_\Omega e_{\alpha\alpha}(\xi^m) e_{\alpha\alpha}(\xi) d\omega d\eta + \frac{2\mu\lambda}{\lambda + 2\mu} \int_\Omega e_{\alpha\beta}(\xi^m) e_{\beta\beta}(\xi) d\omega d\eta = \eta_m(0) \int_\Omega \xi_\alpha^m \xi_\alpha d\omega d\eta.
\]

(5.26) comes using relations (2.2).

□

Lemma 5.9. For each \(m \geq 1\), the whole family \((\eta_\varepsilon^m(\varepsilon))_{\varepsilon \to 0}\) converges as \(\varepsilon \to 0\). In addition, if \(\eta_m(0)\) is a simple eigenvalue of (5.26), then \(\eta_\varepsilon^m(\varepsilon)\) is also a simple eigenvalue of (3.5) for \(\varepsilon < \varepsilon_0\) small enough.

Proof. See [7].

□

Proposition 5.10. For each \(m \geq 1\), the limit eigensolutions \((\eta_m(0), \xi_1^m, \xi_2^m)\) verify the classical equations of stretching vibrations:

\[
\begin{align*}
\frac{E}{2(1 - \nu^2)} \left[ 2 \frac{\partial^2 \xi_1^m}{\partial x_1^2} + (1 - \nu) \frac{\partial^2 \xi_1^m}{\partial x_2^2} + (1 + \nu) \frac{\partial^2 \xi_2^m}{\partial x_1 \partial x_2} \right] &= \eta_m(0) \xi_1^m, \\
\frac{E}{2(1 - \nu^2)} \left[ 2 \frac{\partial^2 \xi_2^m}{\partial x_2^2} + (1 - \nu) \frac{\partial^2 \xi_2^m}{\partial x_1^2} + (1 + \nu) \frac{\partial^2 \xi_1^m}{\partial x_1 \partial x_2} \right] &= \eta_m(0) \xi_2^m,
\end{align*}
\]

(5.27)

with

\[
\xi_1^m = \xi_2^m = 0 \quad \text{on} \quad \gamma.
\]

(5.28)
Proof. Performing an integrating by part in the left-hand side of Eq (5.26) we obtain, for all \((\xi_1, \xi_2) \in [H^1_0(\omega)]^2\)

\[
\frac{E}{1 + \nu} \int_\omega \left[ \frac{\partial^2 \zeta_1^m}{\partial x_1^2} + \frac{1}{2} \frac{\partial^2 \zeta_1^m}{\partial x_2^2} + \frac{1}{2} \frac{\partial^2 \zeta_2^m}{\partial x_1^2 \partial x_2} \right] \xi_1 dx_1 dx_2 \\
+ \frac{E}{1 + \nu} \int_\omega \left[ \frac{\partial^2 \zeta_2^m}{\partial x_2^2} + \frac{1}{2} \frac{\partial^2 \zeta_2^m}{\partial x_1^2} + \frac{1}{2} \frac{\partial^2 \zeta_1^m}{\partial x_1 \partial x_2} \right] \xi_2 dx_1 dx_2 \\
+ \frac{Ev}{1 - \nu^2} \int_\omega \left[ \frac{\partial^2 \zeta_1^m}{\partial x_1^2 \partial x_2} + \frac{\partial^2 \zeta_2^m}{\partial x_1 \partial x_2} \right] \xi_1 dx_1 dx_2 \\
+ \frac{Ev}{1 - \nu^2} \int_\omega \left[ \frac{\partial^2 \zeta_2^m}{\partial x_2^2} + \frac{\partial^2 \zeta_1^m}{\partial x_1^2} \right] \xi_2 dx_1 dx_2 \\
= \eta_m(0) \int_\omega \zeta_1^m \xi_1 dx_1 dx_2 \\
+ \eta_m(0) \int_\omega \zeta_2^m \xi_2 dx_1 dx_2.
\]

which gives, for all \((\xi_1, \xi_2) \in [H^1_0(\omega)]^2\)

\[
\frac{E}{2(1 - \nu^2)} \int_\omega \left[ \frac{2}{2} \frac{\partial^2 \zeta_1^m}{\partial x_1^2} + (1 - \nu) \frac{\partial^2 \zeta_1^m}{\partial x_2^2} + (1 + \nu) \frac{\partial^2 \zeta_2^m}{\partial x_1 \partial x_2} \right] \xi_1 dx_1 dx_2 \\
+ \frac{E}{2(1 - \nu^2)} \int_\omega \left[ \frac{2}{2} \frac{\partial^2 \zeta_2^m}{\partial x_2^2} + (1 - \nu) \frac{\partial^2 \zeta_2^m}{\partial x_1^2} + (1 + \nu) \frac{\partial^2 \zeta_1^m}{\partial x_1 \partial x_2} \right] \xi_2 dx_1 dx_2 \\
= \eta_m(0) \int_\omega \zeta_1^m \xi_1 dx_1 dx_2 + \eta_m(0) \int_\omega \zeta_2^m \xi_2 dx_1 dx_2.
\]

(5.27) is obtained by taking respectively \(\xi_2 = 0\) and \(\xi_1 = 0\).

6. Conclusions

In this work, we have proved that the stretching frequencies of an elastic thin plate is the limit of a family of high frequencies of the three-dimensional elastic model of the plate, as the thickness approaches zero. We have also shown, that the standard spectral problem associated to stretching modes in linear elastic plates can be derived mathematically from the standard three-dimensional eigenvalue problem of linear elasticity through a non-standard asymptotic analysis technique. This technique can be used to study a wide variety of problems of modeling vibrations for thin structure like folded plate and junction between different thin structures.
