Abstract: Cryptography serves as the cornerstone for safe communication and data security in today's digital environment. Because they feature substitution boxes, substitution-permutation networks (SPNs) are crucial for cryptographic algorithms such as the popular Advanced Encryption Standard (AES). The structure and properties of S-boxes have a significant impact on the overall security of cryptographic systems. This article aims to improve cryptographic security through unique S-box construction methodologies. The proposed S-boxes improve the security features by employing chaotic maps and Galois fields, which go beyond traditional design approaches. The S-boxes were analyzed and the weaknesses were removed to design strong candidate S-boxes. The efficiency of the proposed S-boxes in increasing cryptographic resilience is thoroughly explored thereby taking nonlinearity, strict avalanche requirements, bit independence constraints, linear approximation, and differential approximation into account. The dynamic S-boxes have average scores of nonlinearity, strict avalanche criteria(SAC), nonlinearity of Bit Independence Criteria (BIC Nonlinearity), SAC of Bit Independence Criteria (BIC SAC), Linear Approximation Probability (LAP) and Differential Approximation Probability (DAP) is 111.1025, <sup>111</sup>.1022, <sup>0</sup>.5014, <sup>0</sup>.5024, <sup>111</sup>.1082, <sup>111</sup>.0964, 0.5024, <sup>0</sup>.5022, <sup>0</sup>.0726, <sup>0</sup>.0729 and <sup>0</sup>.0214, <sup>0</sup>.0219, respectively. Furthermore, given the prevalence of images in modern communication and data storage, this work studies the seamless incorporation of advanced S-boxes into image encryption systems. With its thorough research, the paper contributes to the current discussion on cryptographic security by providing theoretical understandings and practical solutions to improve digital communication and data security in an era of rising cyber dangers and ubiquitous connectivity.

Keywords: affine matrices; cryptanalysis; encryption; hyperchaos; S-box Mathematics Subject Classification: 94A60, 68P25

### 1. Introduction

Personal information secrecy is something that many people want to keep private, and this requirement has always been present. There are several examples when it is necessary to protect sensitive data from prying eyes. It is crucial to stop enemies from listening in on conversations between military commanders or monarchs and their soldiers. Simple techniques have been previously used to obfuscate data. However, as society has developed and became more networked, there has been a significant rise in the dependence on electronic technologies [\[1\]](#page-20-0). As a result, there is now a greater need for electronic services, and sharing private information online is commonplace. As a result, the need for sophisticated data security methods has become more crucial in our day-to-day lives. The main goal of cryptography is to provide a safe network communication. Ensuring the security of information is often the main goal of cryptography [\[2\]](#page-21-0). Modern cryptography has evolved from a variety of fields, including computer science, mathematics, communication science, physics, and electrical engineering. Numerous real-world situations include the use of cryptography, such as safeguarding chip-based payment cards, enabling digital currencies, securing computer passwords, and expediting Internet commerce.

Cryptographic techniques play a pivotal role in safeguarding sensitive information from prying eyes, and their effectiveness hinges on the robustness of cryptographic components, such as substitution boxes (S-boxes). The need for robust S-boxes has led researchers to explore various techniques for their development. In the work referenced as [\[3\]](#page-21-1), Cao Y. and Cui L. introduced a novel S-box structure known as Affine-Power-Affine (APA). The authors in [\[4\]](#page-21-2) created an S-box using a chaotic map. Additionally, in the research conducted by X. Wang and Q. Wang, as documented in [\[5\]](#page-21-3), dynamic S-boxes were crafted using chaos techniques. In another approach detailed in [\[6\]](#page-21-4), Shah *et al*. harnessed the actions of the symmetric group  $S_8$  on the Advanced Encryption Standard (AES) S-box to derive a substitution box. Another intriguing method, outlined in [\[7\]](#page-21-5), employed a chaotic system to generate a series of S-boxes, where each was considered as a circular sequence with an initial pointer position. These S-boxes were selected to replace individual pixel values in images, and the selected S-boxes were dynamically updated by shifting the pointer forward based on the ciphered pixel and a randomly chosen integer. Furthermore, an alternative algorithm was proposed in [\[8\]](#page-21-6), where the authors applied the group  $PGL(2, GF(2^8))$  action on  $GF(2^8)$  to design an S-box. Ali *et al.* [\[9\]](#page-21-7) used the composition of a homomorphism of the group  $\mathbb{Z} \times \mathbb{Z}$  and inverse mapping of  $GF(2^8)$  to design a large number of a homomorphism of the group  $\mathbb{Z}_{16} \times \mathbb{Z}_{16}$  and inverse mapping of  $GF(2^8)$  to design a large number of robust S-boxes with a minimal computation time. This scheme can have S-boxes with a nonlinearity less than 112.

Chaotic systems offer a viable strategy to design S-boxes. Chaotic systems are sensitive to starting circumstances, thus making them suitable to create pseudorandom sequences. This characteristic may be utilized to generate encryption keys that are hard to predict. The authors in [\[10\]](#page-21-8) studied how the unpredictability in chaotic maps is related to the Lyapunov exponent (LE). There were some drawbacks to using the newly created chaotic map in cryptography. These drawbacks included low randomness, a weak positive LE, and the absence of ergodicity in the phase space. In order to get over these restrictions and show how LE and randomness are related, the authors first built a generic n-dimensional non-degenerate hyper chaotic map (nD-NDCM) model with an adjustable LE using the Jacobian matrix's eigenvalues. Additionally, using this model as the basis, the authors instantiated 2D-NDCM and 3D-NDCM, and then examined their dynamic performance using the bifurcation diagrams, phase diagrams, and LE. Chaotic systems can develop diffusion procedures necessary for picture encryption. The authors in [\[11\]](#page-21-9) designed a new strategy to design the fractional transformation of a finite field using the 2D Arnold map. The authors employed a chaotic logistic map for dynamically key dependent S-boxes. A new chaotic S-box was designed in [\[12\]](#page-21-10) using the randomness of the LU Chen chaotic system. The authors designed two S-boxes with a substantial nonlinearity of 105–106 by employing row column permutations and a zigzag transformation. Ali *et al*. explored the applications of the Frobenius automorphism in [\[13\]](#page-21-11). The authors composed the linear fractional transformation with Frobenius map of the said field to design two new fractional transformations of degree 2. This mapping generates highly nonlinear and robust S-boxes. Additionally, the authors used a logistic map for dynamic generation. [\[14\]](#page-21-12) proposed a unique picture encryption system based on an S-box formed by a mutation and crossover. [\[15\]](#page-21-13) Lai and Hu introduced a revolutionary medical picture encryption strategy that blended compressive sensing techniques with a customised memristive hyperchaotic system. The suggested approach may swiftly encrypt a large quantity of medical photos into a custom-sized cypher image, thus significantly increasing the algorithm's efficiency. The S-box has a nonlinearity of 111.25, which is a good score on other aspects, with no fixed or reverse fixed points. The authors in [\[16\]](#page-22-0) suggested a 4D memcapacitive hyperchaotic logistic map (4D-MHLM) that incorporated memcapacitors into the logistic map. The dynamical behavior of the 4D-MHLM was investigated using the Lyapunov exponent assessment, and the effects of various parameters on the system performance was examined. The complexity of producing pseudo-random sequences with the 4D-MHLM was explored using complexity analysis, which included spectral entropy and C0 complexity. The study in [\[17\]](#page-22-1) suggested a method to improve the communication security through facial detection and chaotic partitioning. The system used an edge detection algorithm to identify facial details, which was subsequently encrypted. The hash value of the plaintext image was taken and used as the private key to the chaotic sequence produced by the system. The facial image underwent encryption processes to produce the final ciphertext. [\[18\]](#page-22-2) used a genetic algorithm-based optimization model. The model employed chaotic sequences to construct initial S-boxes, and then nonlinearity was adjusted by treating it as an objective function. The average nonlinearity for the S-boxes was 110.25. The study [\[19\]](#page-22-3) introduced an oscillatory term to discrete memristor (DM) models, thus creating four hyperchaotic maps with hidden attractors and diverse dynamical behaviors. These maps, validated through hardware implementation, generated highly random sequences, which were successfully applied in pseudorandom number generators (PRNGs). A non-degenerate 3D hyperchaotic map was designed for image encryption and an S-box in [\[20\]](#page-22-4). The authors eliminated the fixed, reverse fixed points ,and the short period rings in the designed S-box. The nonlinearity of the proposed scheme remained less than 112. Liu *et al.* [\[21\]](#page-22-5) defined a new 2D hyperchaotic map to generate random affine invertible matrices over the binary field . They designed keyed S-boxes and introduced a mechanical

way to eradicate the existing weakness. The elimination process effected the nonlinearity, and its average was 110.60. The authors in [\[22,](#page-22-6)[23\]](#page-22-7) devised a similar methodology to eliminate the weaknesses in S-boxes, where the design was dependent upon a hyperchoatic map and algebraic transformations.

Based on the detailed analysis of existing literature, we have found that if an S-box is designed using Chaos, then its nonlinearity is very low and we have to use an optimization model as an extra layer to enhance the strength. The S-box designed based on algebraic transformations have other types of weaknesses, such as the existence of a fixed point, reverse fixed points, and short period cycles. A recent study in [\[12,](#page-21-10) [13\]](#page-21-11) showed that employing chaotic mappings with algebraic transformations can be beneficial in terms of the nonlinearity, key dependence, complexity ,and the weaknesses. In this article, our primary goal is to bolster image security within cryptographic frameworks by advancing the state-of-the-art S-box design. To achieve this objective, we embark on a journey through the realm of mathematical structures, specifically the newly designed hybrid hyperchaotic map,  $4 \times 4$  invertible matrices, and Galois fields. These mathematical constructs serve as the building blocks for the creation of novel S-boxes that exhibit remarkable security features. By harnessing the inherent properties of these structures, we enhance the resistance of S-boxes against a multitude of cryptographic attacks, thus ensuring that sensitive visual data remains protected. Our endeavor extends beyond theoretical development, as we rigorously assess the cryptographic performance of these newly devised S-boxes. Through a meticulous analysis that encompasses nonlinearity, strict avalanche criteria, bit independence criteria, linear approximation, and differential approximation, we provide empirical evidence of the enhanced security offered by these S-boxes. The designed S-boxes have no weaknesses such as fixed points, reverse fixed points, and short period cycles. Moreover, recognizing the practical significance of our research, we delve into the seamless integration of these sophisticated S-boxes into image encryption systems. This integration not only fortifies the security of visual data, but also paves the way for more resilient and reliable cryptographic practices in the realm of image security.

### *1.1. Motivations and contributions*

The following are our motivations for this article:

- (1) Developing new hybrid hyperchaotic maps with strong randomness and a large key space;
- (2) Incorporating chaotic maps to generate dynamic S-boxes with Galois fields; and
- (3) Designing highly nonlinear S-boxes without any weakness.

The contributions of the proposed study are as follows:

- (1) A new 2D hybrid hyperchaotic map with a key space of  $2.7378 \times 10^{54}$  is designed;
- (2) This scheme can generate millions of strong candidate S-boxes with any weakness; and
- (3) The average scores of candidate S-boxes are better than existing schemes available in the literature.

The rest of the article is divided into four main sections: In Section [2,](#page-4-0) we introduce a new hybrid hyperchaotic map; in Section [3,](#page-6-0) we create some S-boxes using the action of matrices on the Galois fields; in Section [4](#page-8-0) carefully analyzes the S-box generated in terms of statistics and compares it with other research in the field; the cryptanalysis is explained in Section [5](#page-15-0) regarding the sensitivity; one of the S-boxes is used in Section [6](#page-17-0) to encrypt different images; the results of this encryption are compared to the findings of previous studies in the literature; Section [7](#page-20-1) sums up the article's main points and provides some ideas for future research in this area.

### <span id="page-4-0"></span>2. Construction of 2D hyperchaotic map

#### *2.1. 2D hyperchaotic map*

A chaotic map with ergodicity and excellent randomness can function as a pseudo random number generator. We created the 2D hyperchaotic map given in Eq [\(2.1\)](#page-4-1) with three parameters using modular operations and represented it as follows:

<span id="page-4-1"></span>
$$
x(i + 1) = r \cdot (1 - a^{\pi + y(i)}) + (r - a) \cdot (1 - x(i)) \pmod{1},
$$
  
\n
$$
y(i + 1) = r \cdot (1 - b^{\pi + x(i)}) + (r - b) \cdot (1 - y(i)) \pmod{1}.
$$
\n(2.1)

<span id="page-4-2"></span>The parameter  $r \in (0, 1800]$ , while a, b are real numbers in [2, 40]. The bifurcation, phase diagrams, and Lyapunov exponents in Figures [1](#page-4-2)[–3](#page-5-0) indicate the ergodicity and randomness in the phase space for the time sequences created by 2D hyperchaotic map. We will use the 2D hyperchaotic map to generate a random affine transformation matrix and three index variables.

**Figure 1.** 3D Bifurcation diagram of Chaotic map with  $a = 3.504946177477956$ ,  $b =$ <sup>19</sup>.835653902506410.

<span id="page-5-0"></span>Figure 2. Phase diagram of Chaotic map with  $a = 8.9958772224860656$ ,  $b =$ <sup>12</sup>.213067941059531.

Figure 3. Lyapunov exponent.

### *2.2. Generation of a*ffi*ne invertible matrices*

The most important step in the construction of the S-box in the proposed algorithm is the generation of affine invertible matrices over  $\mathbb{F}_2$ . For this, we iterated the 2D hyperchaotic for 1020 iterations. The two matrices are calculated as:

Discard the first 1000 iterations and define *A* and *B* by the following:

$$
A = \text{reshape}\left( \left( \lfloor x_{1001:1016} \times 10^{16} \rfloor, 2 \right), 4, 4 \right) \pmod{2},
$$

*AIMS Mathematics* Volume 9, Issue 12, 36116–36139.

$$
B = \text{reshape}\left( \left( \lfloor y_{1001:1016} \times 10^{16} \rfloor, 2 \right), 4, 4 \right) \pmod{2}.
$$

Calculate the determinant of both matrices, and if both are invertible over *GF*(2), then we will proceed further; otherwise, we will modify both initial conditions. The two-column vectors are defined as follows:

$$
b = (\lfloor x_{1017:1020} \times 10^{16} \rfloor) \pmod{2},
$$
  

$$
c = (\lfloor y_{1017:1020} \times 10^{16} \rfloor) \pmod{2}.
$$

Meanwhile, we also use the given new chaotic map for the selection of irreducible polynomials of degree 4 and 8 to generate finite fields with 16 and 256 elements. The three index variables are defined as follows:

> Index<sub>1</sub> = mod  $(|x_{1001} \times 256|, 3) + 1$ ,  $Index_2 = \text{mod } (|y_{1002} \times 256|, 3) + 1$ , Index<sub>3</sub> = mod  $([x<sub>1003</sub> \times 256], 30) + 1$ .

The irreducible polynomials of degree 4 are as follows:

$$
p(x) = x4 + x + 1 (19),
$$
  
\n
$$
q(x) = x4 + x3 + 1 (25),
$$
  
\n
$$
r(x) = x4 + x3 + x2 + x + 1 (31).
$$

### <span id="page-6-0"></span>3. Generation of S-Box

Consider two finite fields  $\mathbb{F}_1$  and  $\mathbb{F}_2$  based on the irreducible polynomials  $p(x)$ ,  $q(x)$ , and  $r(x)$  then, the maps  $\phi : \mathbb{F}_1 \to \mathbb{F}_1$ ,  $\psi : \mathbb{F}_2 \to \mathbb{F}_2$  defined by  $\phi(x) = Ax^{-1} + b$ ,  $\psi(x) = Bx^{-1} + c$  are bijective iff *A* and *B* are invertible matrices over  $\mathbb{F}_2$ , whereas *b*, *c* are binary column vectors of size  $4 \times 1$ . Let  $g(x)$  be the inversion map of the Galois field concerning irreducible polynomials of the list available in [\[13\]](#page-21-11). The algorithm to design the S-box is as follows:

(1) Convert each entry of  $\mathbb{F}_1$  and  $\mathbb{F}_2$  into binary.

(2) Apply the maps  $\phi$ ,  $\psi$  on binary entries of  $\mathbb{F}_1$  and  $\mathbb{F}_2$ , and convert back to the decimal entries. Store the results in two sets *C* & *D*.

(3) Take the Cartesian product of the sets *C* and *D* and concatenate the bits to obtain a  $16 \times 16$  matrix of entries 0 − 255. Store the results in *f* .

(4) Define the S-boxes  $S_1$  and  $S_2$  by following two rules:

$$
\bullet \ \ S_1 = f \circ g.
$$

$$
\bullet \ \ S_2 = g \circ f.
$$

#### *3.1. Elimination of weakness*

There are some flaws in S-box designs, such as having fixed points, reverse fixed points, and short period cycles. The cryptographer aims to develop a highly nonlinear S-box that does not have a fixed point, reverse fixed point, or short-period cycles. For the elimination of weakness, we consider the method as developed in [\[21\]](#page-22-5).

36123

Two Sample candidate S-boxes are displayed in Tables [1](#page-7-0) and [2,](#page-7-1) which were obtained by fixing  $x_0$  = 0.150591199468996,  $y_0$  = 0.888238060843572,  $a$  = 6.401634045456396, and  $b$  = <sup>19</sup>.376372433391815.

### <span id="page-8-0"></span>4. Statistical analysis and security evaluation of the S-boxes

In this context, we have presented the security assessment of our proposed S-boxes to confront potential cryptographic vulnerabilities. The S-boxes have been subjected to a series of evaluations. The obtained results have been compared against established S-boxes of repute. An explanation of the conducted tests is provided in the following section.

### *4.1. Nonlinearity (NL)*

The concept of "nonlinearity" in this context was formally introduced by Pieprzyk and Finkelstein in 1988, as documented in [\[24\]](#page-22-8). Nonlinearity quantifies the disparity between an nth-variable Boolean function and the entire set of affine functions of n variables. The highest achievable nonlinearity for S-boxes constructed using  $GF(2^8)$  $GF(2^8)$  $GF(2^8)$  is [1](#page-7-0)20. The sample S-boxes of Tables 1 and 2 achieved the nonlinearity of 112 displayed in Table [3.](#page-8-1) Among randomly generated 1000 S-boxes, 239 and 223 are of the nonlinearity 112 by both composition functions. The average nonlinearity after removing the fixed, reverse fixed points, and short cycles stood at 111.1025 and 111.1022. The similar kind of scheme in [\[21\]](#page-22-5) has the nonlinearity 110.60. However, our scheme produced better results as compared to the existing schemes. Meanwhile, most of the S-boxes have a nonlinearity greater than 110, as can be observed from the pie charts in Figures [4](#page-9-0) and [5.](#page-9-1)

<span id="page-8-1"></span>

S-boxes	<b>Mathematical Structure</b>	Nonlinearity	<b>SAC</b>	<b>BIC Nonlinearity</b>	<b>BIC SAC</b>	LAP	<b>DAP</b>

# *4.2. Strict Avalanche Criteria (SAC)*

This evaluation assesses the degree of fluctuation in the output resulting from a slight modification in the input value. The concept of Strict Avalanche Criteria ( SAC) (i.e., Sensitivity to Input Changes) was pioneered by Tavares and Webster, as documented in their work [\[37\]](#page-23-7). According to the SAC

criterion, when a single input bit of the S-box is inverted, it is expected that exactly 50% of the output bits will, on average, undergo an inversion as well. The formula for the essential dependence matrix, denoted as "M," required for SAC is expressed as follows:

$$
M(x) = \frac{\sum_{k=1}^{8} h(x) \oplus h(x \oplus y_j)}{256} \quad ; \quad HWT(y_j) = 1 \quad \forall \quad j = 1, 2, ..., 8. \tag{4.1}
$$

<span id="page-10-0"></span>The average SAC score in [\[21\]](#page-22-5) was 0.4966 while, our scheme has 0.5014, <sup>0</sup>.5024 for both composition functions. The overall distribution of the SAC score can be observed in Figures [6](#page-10-0) and [7.](#page-10-1)

Figure 6. SAC Distribution for 2nd Candidate S-box.

<span id="page-10-1"></span>

Figure 7. SAC Distribution for 1st Candidate S-box.

### *4.3. Bit Independence Criteria (BIC)*

The Bit Independence Criteria (BIC) serves as a metric to gauge the cryptographic robustness of an S-box. It quantifies the level to which the output bits of an S-box exhibits independence from the input bits. A greater degree of autonomy between the input and output bits is sought after, as it <span id="page-11-0"></span>enhances the difficulty for potential attackers attempting to analyze and compromise the cryptographic system. The average values of the BIC Nonlinearity and the BIC SAC in [\[21\]](#page-22-5) were 0.5026 and 109.67, while our proposed technique report values of  $111.1082, 111.0964$ , and  $0.5024, 0.5022$ . Thus, our technique outperforms the existing similar techniques in literature. The BIC Nonlinearity and SAC distribution can be observed in Figures [8–](#page-11-0)[11.](#page-12-0)

Figure 10. BIC SAC Distribution for 1st Candidate S-box.

<span id="page-12-0"></span>

Figure 11. BIC SAC Distribution for 2nd Candidate S-box.

# *4.4. Linear Approximation Probability (LAP)*

The Linear Approximation Probability (LAP) test is a powerful cryptanalysis tool designed to assess the robustness of an S-box in block ciphers. This test quantifies the probability of a linear connection between the input and output bits of an S-box. The LAP test operates by examining a set of input and output pairs linked with the S-box and calculating the correlation between these input and output bits using a statistical method. The correlation value indicates the level of linearity in the

relationship between the input and output bits of the S-box.

$$
LAP = \max_{u,v \neq 0} \left| \frac{\left| \left\{ \alpha \in GF(2^8) \mid u \cdot \alpha = v \cdot S(\alpha) \right\} \right| - 128}{256} \right| \tag{4.2}
$$

<span id="page-13-0"></span>The average LP for 1000 S-boxes using both composition functions is 0.0726, <sup>0</sup>.0729 (Figures [12](#page-13-0) and [13\)](#page-13-1), which is far good against the score of 0.0790 in [\[21\]](#page-22-5). The lowest value of 0.0625 is attained by 237 and 218 S-boxes produced by our scheme. This scheme has better scores of LP on the individual and collective levels.

<span id="page-13-1"></span>Figure 12. LP Distribution for 1st Candidate S-box.

Figure 13. LP Distribution for 2nd Candidate S-box.

### *4.5. Di*ff*erential Approximation Probability (DAP)*

The Differential Approximation Probability (DAP) test employs a statistical methodology to gauge the likelihood of a differential relationship. Rather than analyzing all the possible input pairs, the DAP test selects a random groups of input pairs and computes the ratio of pairings that adhere to the defined differential relationship. A larger subset selection results in a more precise estimation of the differential probability. Typically, the DAP test is utilized alongside other statistical tests, such as the LAP test, to conduct a comprehensive assessment of an S-box's security properties as follows:

$$
DP(\Delta u, \Delta v) = \frac{|\{u \in GF(2^8) \mid S(u) \oplus S(u \oplus \Delta u) = \Delta v\}|}{256},\tag{4.3}
$$

where ∆*u* and ∆*v* represents the input and output differential, respectively.

<span id="page-14-0"></span>The DP values for both composition functions can be observed in Figures [14](#page-14-0) and [15](#page-15-1) with a sound score close to [\[21\]](#page-22-5). There are 216 and 223 S-boxes with a DP score of 0.0156.

Figure 15. DP Distribution for 2nd Candidate S-box.

# <span id="page-15-0"></span>5. Cryptanalysis

*5.1. Sensitivity analysis*

# *5.2. Sensitivity with AES S-box*

<span id="page-15-2"></span>We randomly generated 1000 S-boxes from both composition functions and measured the hamming distances between each S-box and AES S-box. The average hamming distances were <sup>1024</sup>.34 and 1023.64, which are very close to the ideal value of 1024. The distribution of hamming distances can be visualized in Figures [16](#page-15-2) and [17.](#page-16-0)

Figure 16. Hamming distance between 1st Candidate S-box and AES S-box.

<span id="page-16-0"></span>

Figure 17. Hamming distance between 2nd Candidate S-box and AES S-box.

### *5.3. Initial key sensitivity*

<span id="page-16-1"></span>We measured the sensitivity of the proposed S-boxes by altering the initial keys. Consider  $x_0$  = 0.046414229568095,  $y_0$  = 0.307869452852334 and  $x_0 + \epsilon$  = 0.046414229568105,  $y_0 + \epsilon$  = 0.307869452852344, where  $\epsilon = 10^{-14}$ . The hamming distance between the candidate S-boxes of the 1st composition is 1024.8 and 1022.9 for 2nd composition. These results are very close to the ideal hamming distance of 1024 and surpass the results of [\[21\]](#page-22-5). The distribution can be observed in Figures [18](#page-16-1) and [19.](#page-17-1)

Figure 18. Hamming distance between 1st Candidate S-boxes.

<span id="page-17-1"></span>

Figure 19. Hamming distance between 2nd Candidate S-boxes.

# <span id="page-17-0"></span>6. Utilization of the envisioned S-box in image encryption

In this section, we utilize our S-box to encrypt various images. We used the Cipher Block Chaining (CBC) mode of AES to encrypt digital photos using the best S box of Table [1](#page-7-0) of our scheme. To assess the performance of the employed image encryption algorithm , we applied the majority logic criterion, which encompasses measures such as Contrast, Entropy, Correlation, Energy, and Homogeneity. The plane and corresponding cipher images are observed in Figures [20](#page-17-2)[–23,](#page-19-0) while the results of the image encryption application are shown in Tables [4](#page-19-1) and [5.](#page-19-2)

### <span id="page-20-1"></span>7. Conclusions

In symmetric cryptosystems, S-boxes are primarily used to create confusion and nonlinearity, which obscures the connection between the key and ciphertext and prevents hackers from obtaining the secret key. In this study, a 2D novel hyperchaotic map was designed with a large key space. The intrinsic nature of the proposed map was used to generate random affine invertible matrices over the binary field. A new approach that employed chaos and finite fields of degree 4 and 8 were introduced to design a large number of S-boxes with a nonlinearity of 112. The weaknesses were identified and removed to obtain candidate S-boxes with substantial nonlinearity in the range of 108 − 112 with an average of 111.1025. A comparative study conducted against well-known S-boxes confirmed the effectiveness and robustness of our suggested method. Moreover, we employed a sample candidate S-boxes to encrypt digital images. In the future, we anticipate creating a diverse range of substitution boxes by employing new permutation polynomials of the Galois field along with new chaotic mappings, and optimization models. Furthermore, we are intrigued by the prospect of utilizing these substitution boxes to encrypt textual content, audio data, and video content.
